# Clustering

---

- ❖ Grouping together similar data points into distinct partitions. Items in same cluster are *more* similar to each other than to the items in other clusters.
- ❖ Common unsupervised machine learning technique.
- ❖ Used for aggregating and summarizing complex multi-dimensional data. Very important exploratory step to understand data before any statistical analysis or data mining.
- ❖ From perception POV, a *scatterplot* is the best way to visualize clusters, often accompanied by a low-dimensional projection (PCA / MDS / tsne) onto 2 dimensions.

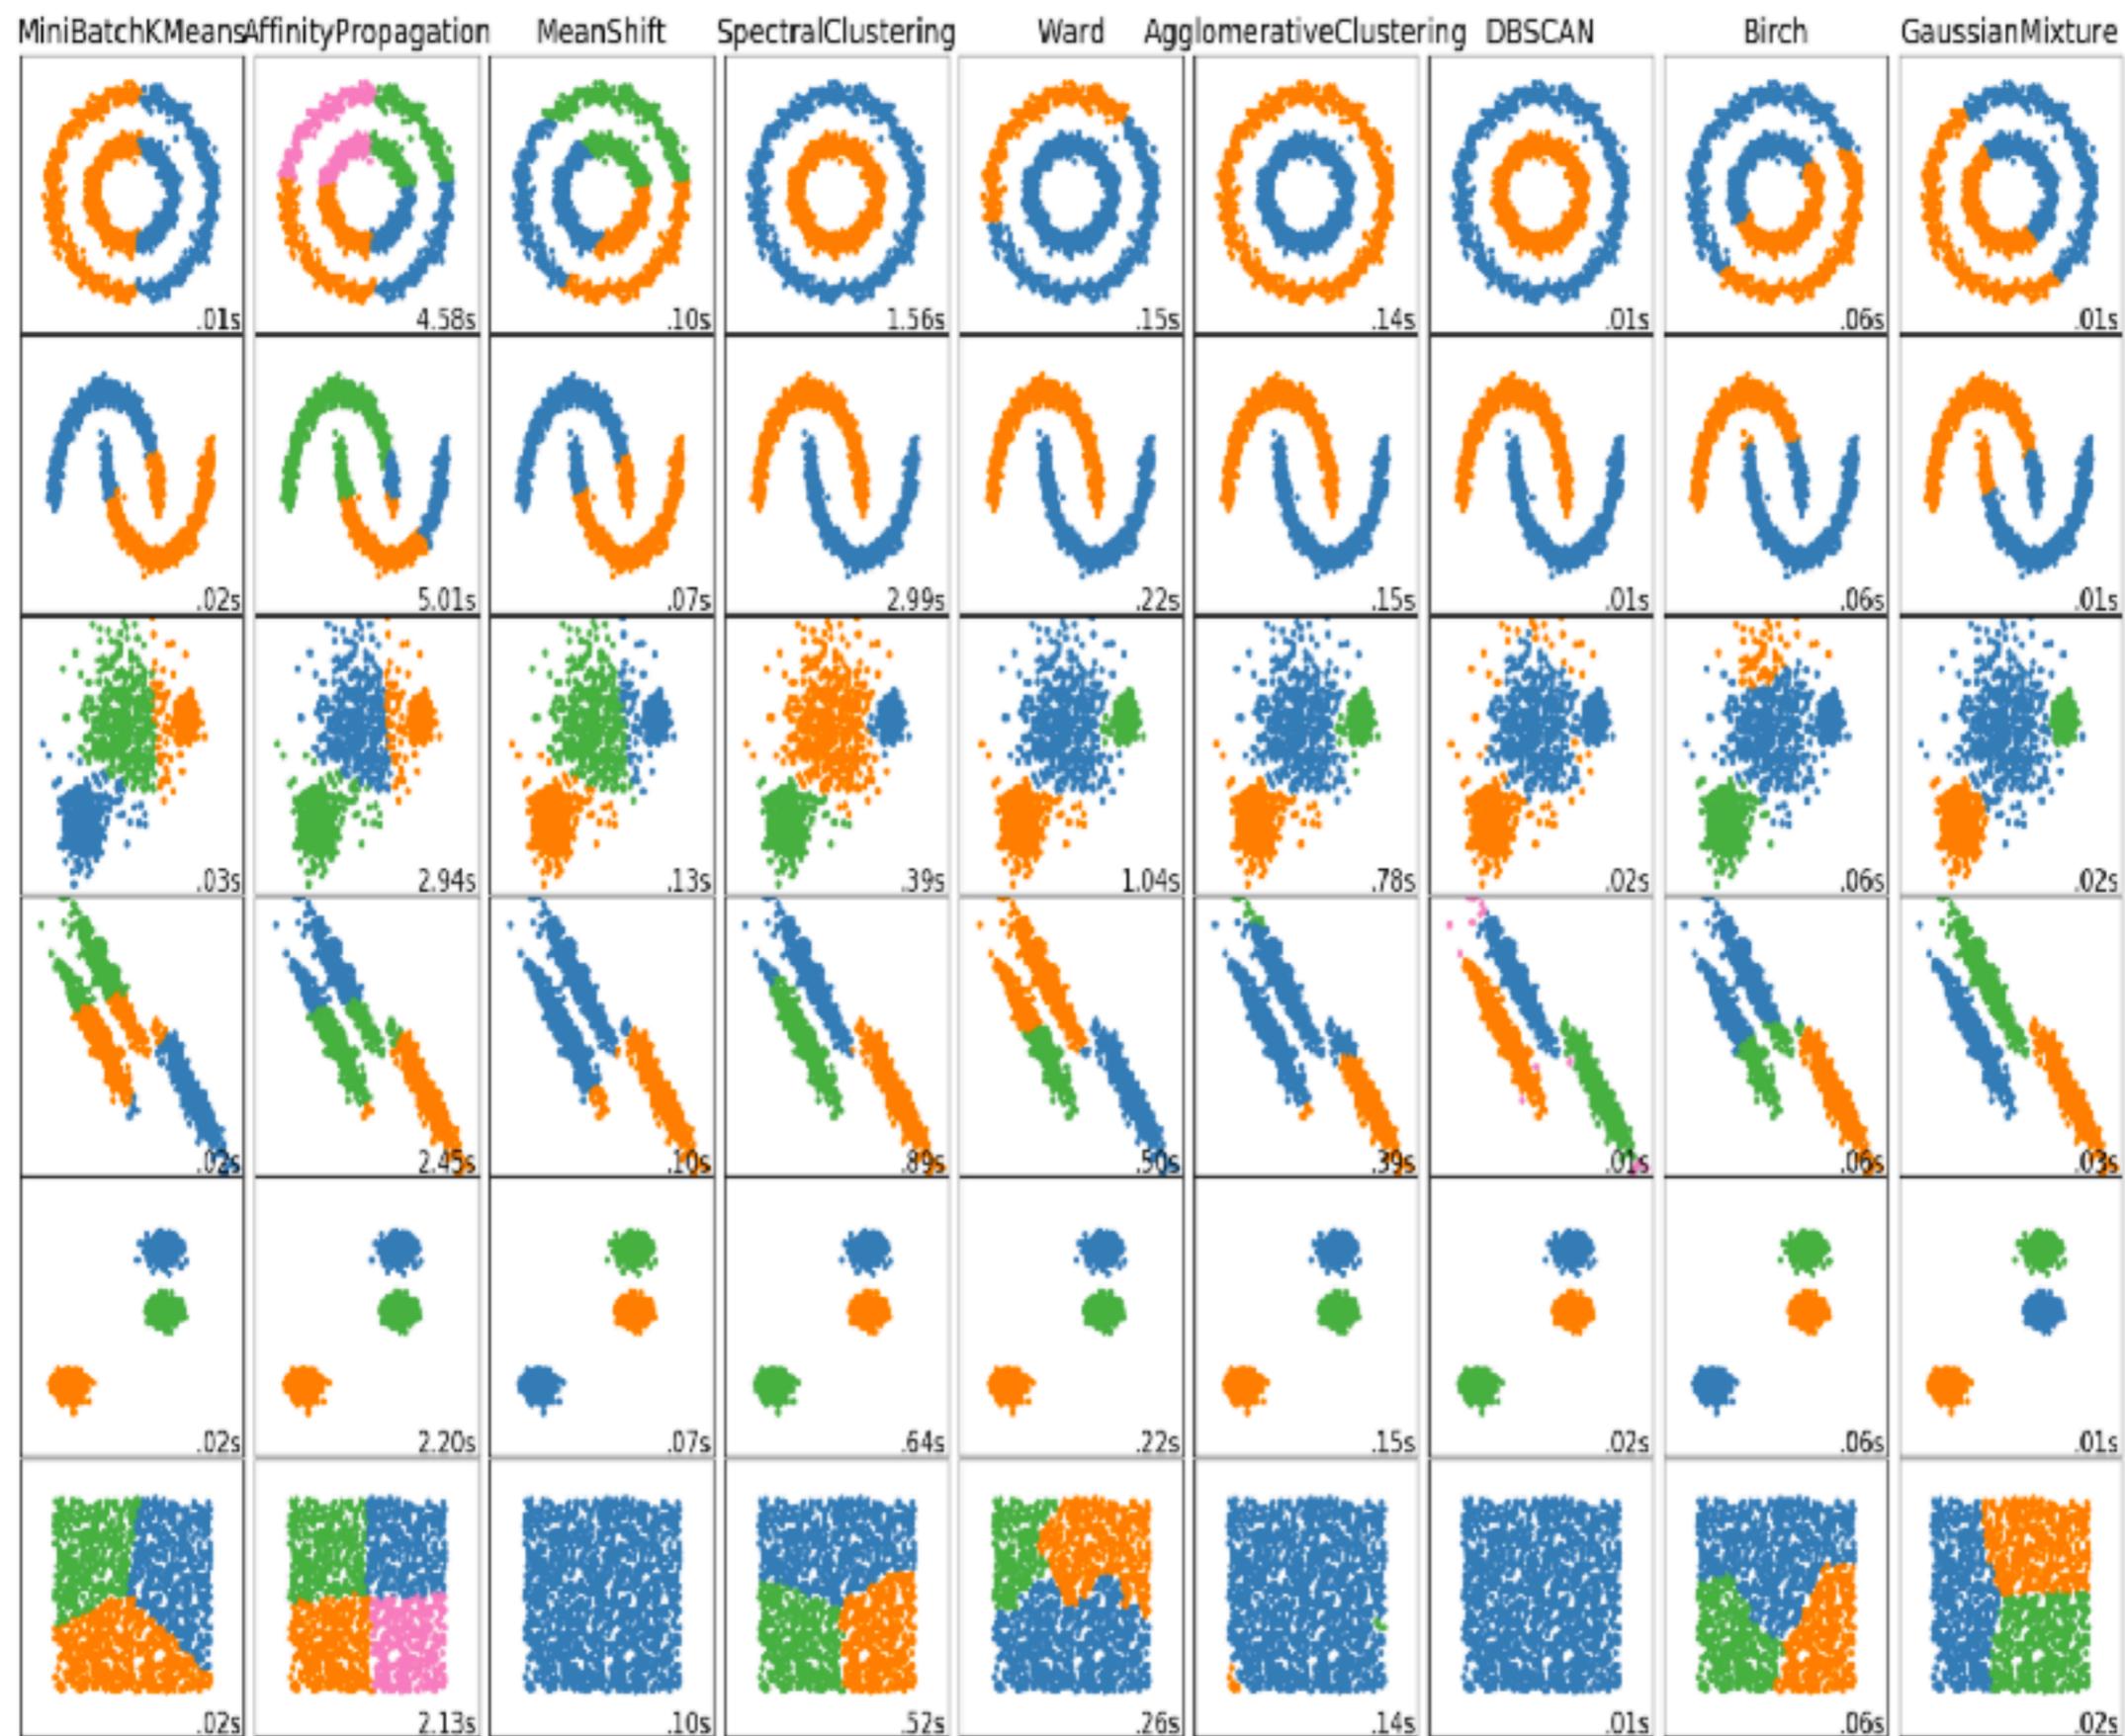

K-means clustering on the digits dataset (PCA-reduced data)  
Centroids are marked with white cross

# Clustering algorithms

---

- ❖ There are a plethora of clustering algorithms that differ in their set of assumptions on data & clusters, and the methods to effectively find clusters.
- ❖ These algorithms have their strengths and weaknesses.
- ❖ The choice of appropriate clustering algorithm and its parameters depend on the individual data set and intended use of the results.
- ❖ However, given a particular dataset and analytical task, there are NO systematic procedures for knowing which algorithm will provide the best clustering.

A comparison of the clustering algorithms in scikit-learn

# Centroid-based Clustering algorithms

---

- ❖ Find cluster representatives, **centroids**, and assign a data point to the cluster whose centroid is the nearest to the data point.
- ❖ Incredibly hard problem: Infinitely many possibilities, NP hard! **Slightly easier version:** k-means, assumes there are k clusters in the data. Still NP hard! Can obtain approximate solution (local minima).
- ❖ **Lloyd's algorithm:** Start with k random centroids, assign points to the nearest centroid, choose new centroid as the mean of the points in the clusters and repeat until a stopping criterion.
- ❖ Partitions data into a *Voronoi diagram*, also related to *Expectation-Maximization*.
- ❖ **Use case:** General-purpose, even cluster size, flat geometry, not too many clusters.
- ❖ **Requires:** choice of metric, apriori knowledge of k.
- ❖ **Drawbacks:** Prefers convex and isotropic clusters, not robust to randomness.
- ❖ **Modifications:** k-medoids, k-medians, k-means++, fuzzy c-means.

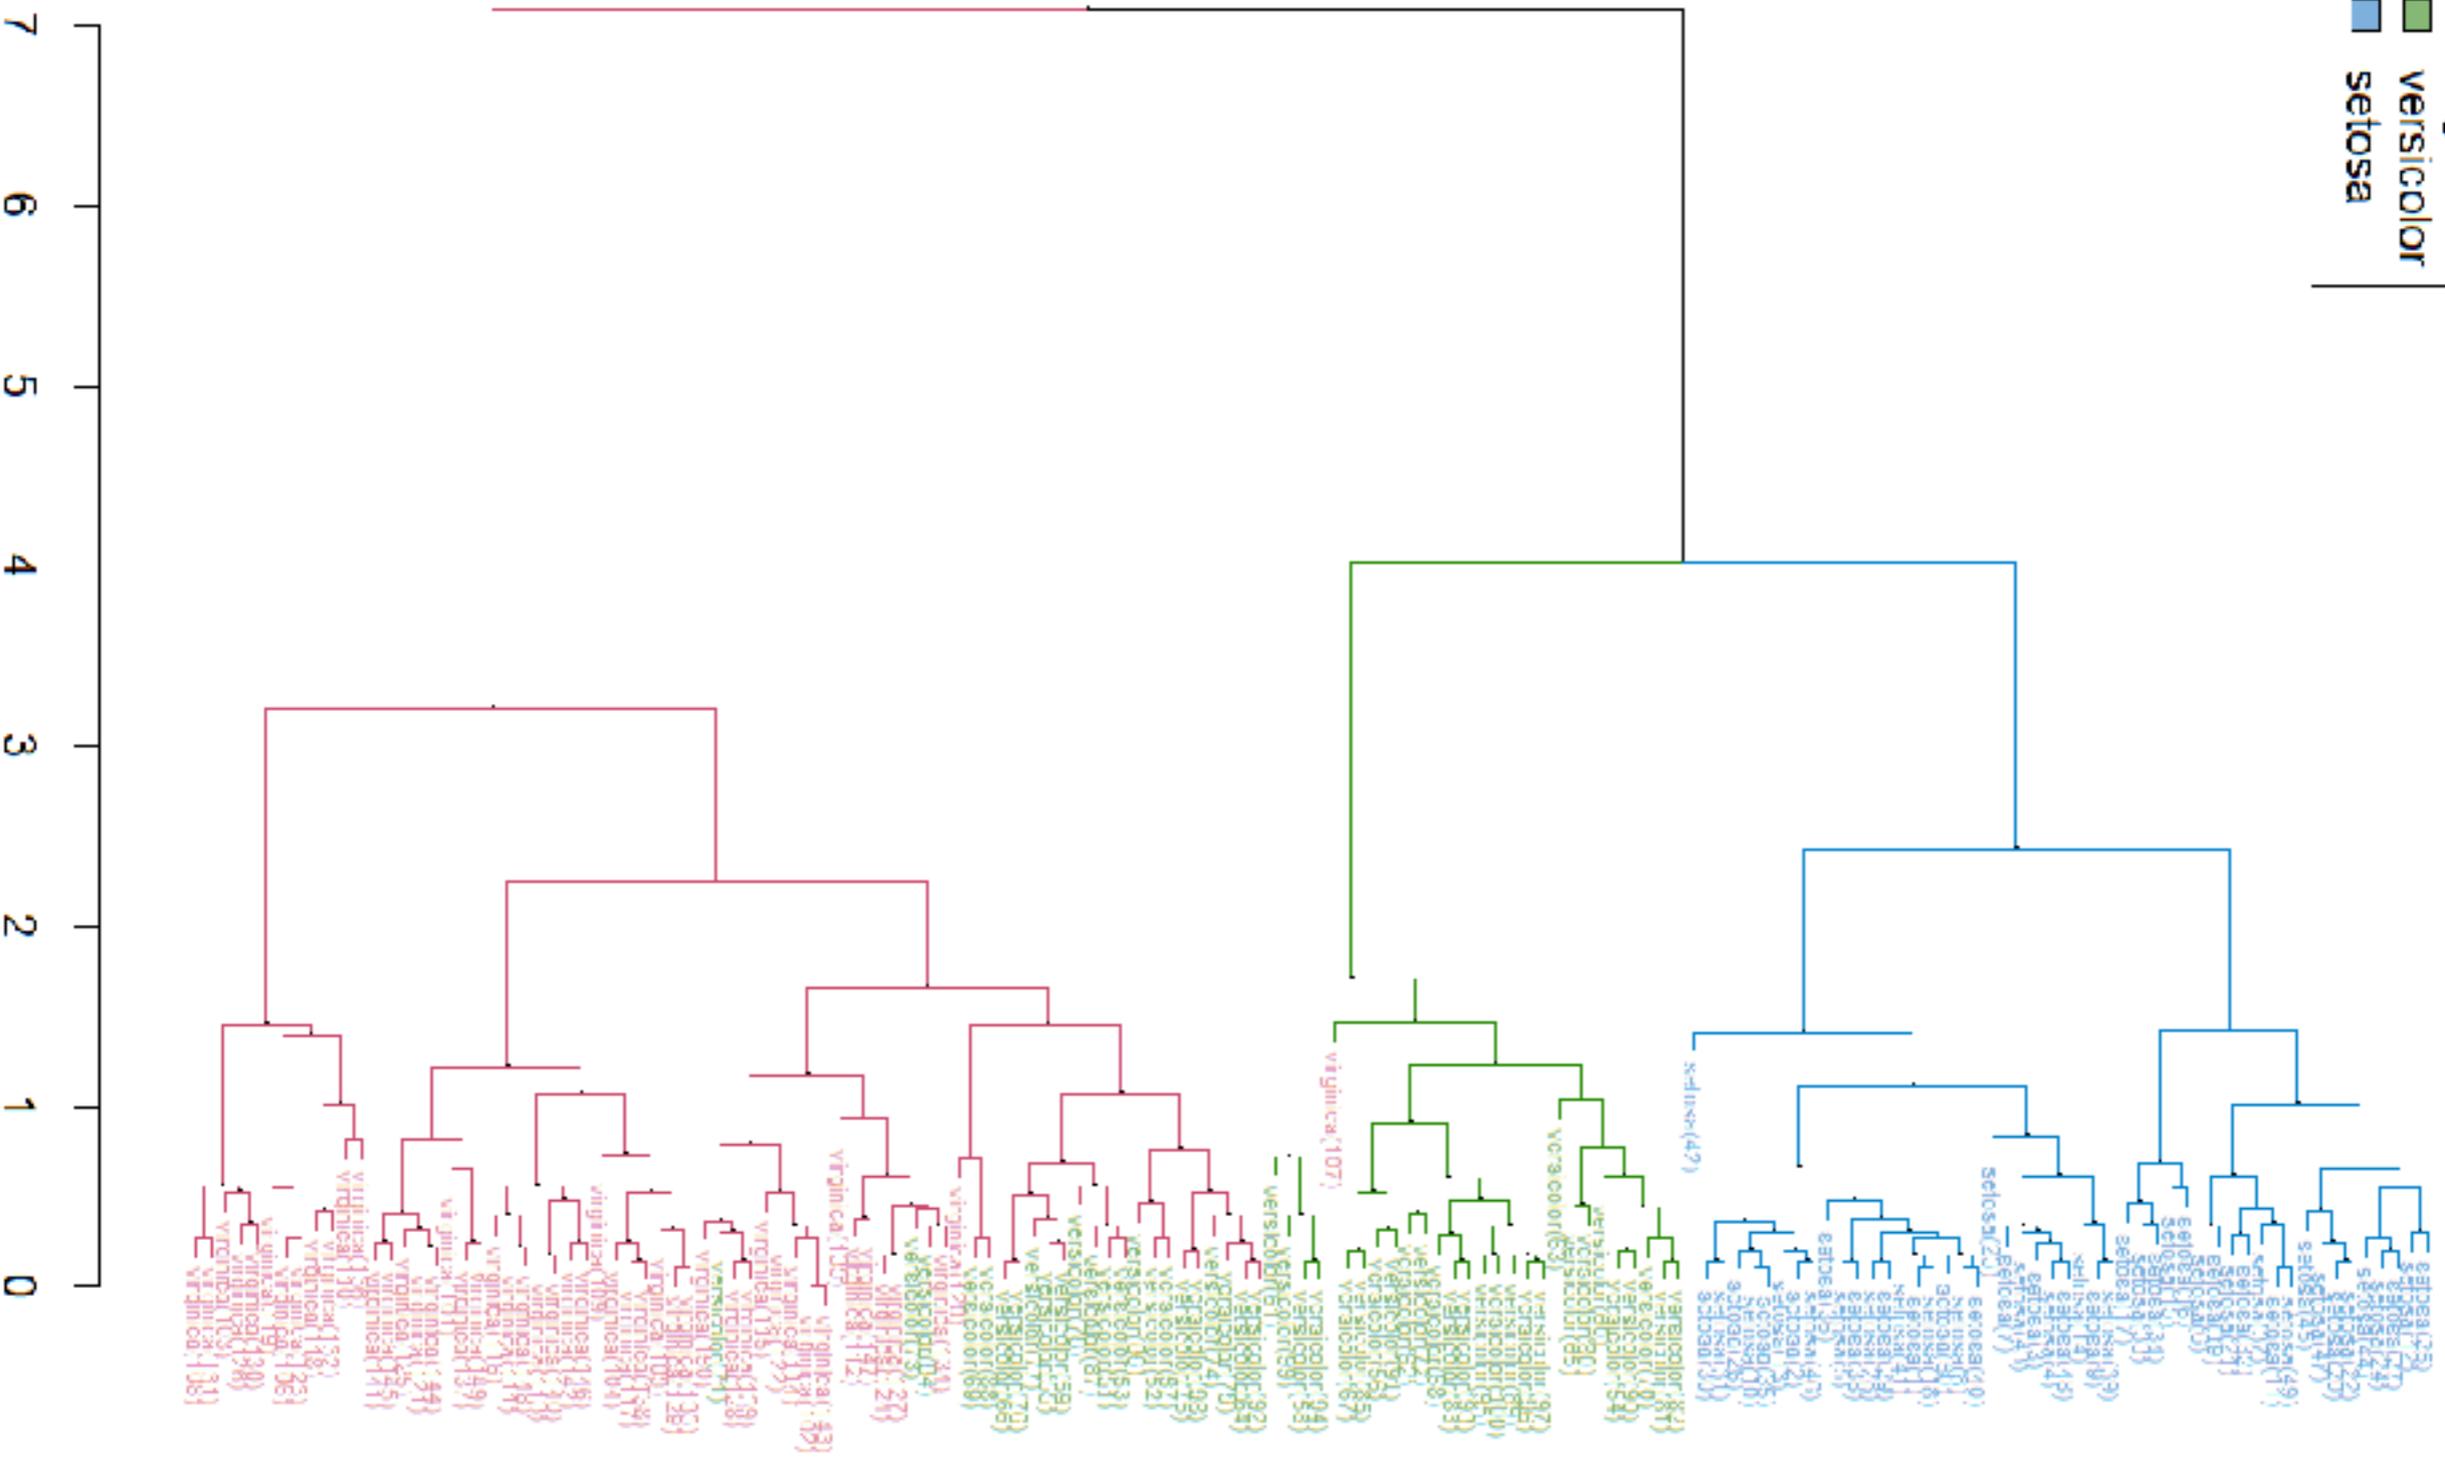

# Connectivity-based clustering algorithms

---

- ❖ **AKA Hierarchical clustering**, provides a nested partitioning of the data by successively merging (*agglomerative*) or splitting (*divisive*) them, thereby producing a hierarchy which can be shown visually as a *dendrogram*.
- ❖ The root of the dendrogram is the unique cluster containing all the data points, and the leaves are clusters each containing exactly one data point.
- ❖ e.g. in *Agglomerative clustering*, each data point starts as an individual cluster and are then merged in successive steps.
- ❖ **Use case:** Many clusters, possibly connectivity constraints, non Euclidean distances.
- ❖ **Requires:** Choice of a metric (distance between two data points), Linkage criterion (distance between two clusters).

- virginica
- versicolor
- setosa

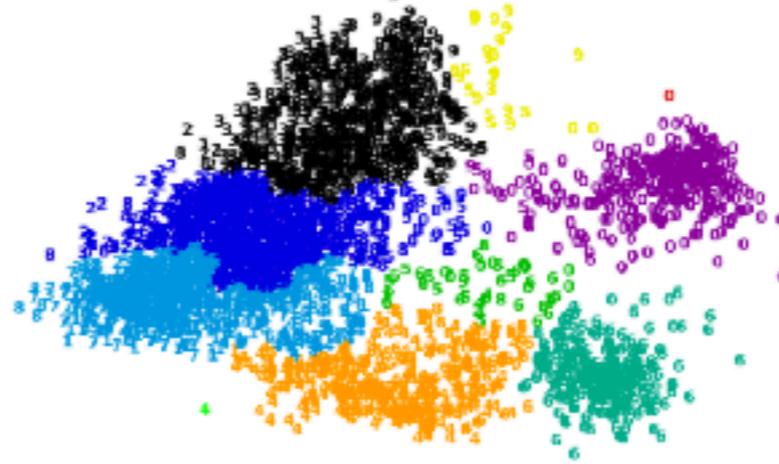

# Different linkages in sklearn

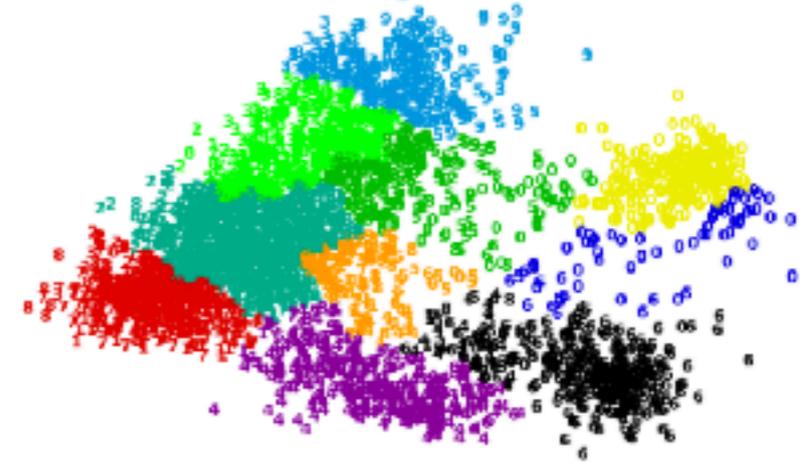

ward linkage

average linkage

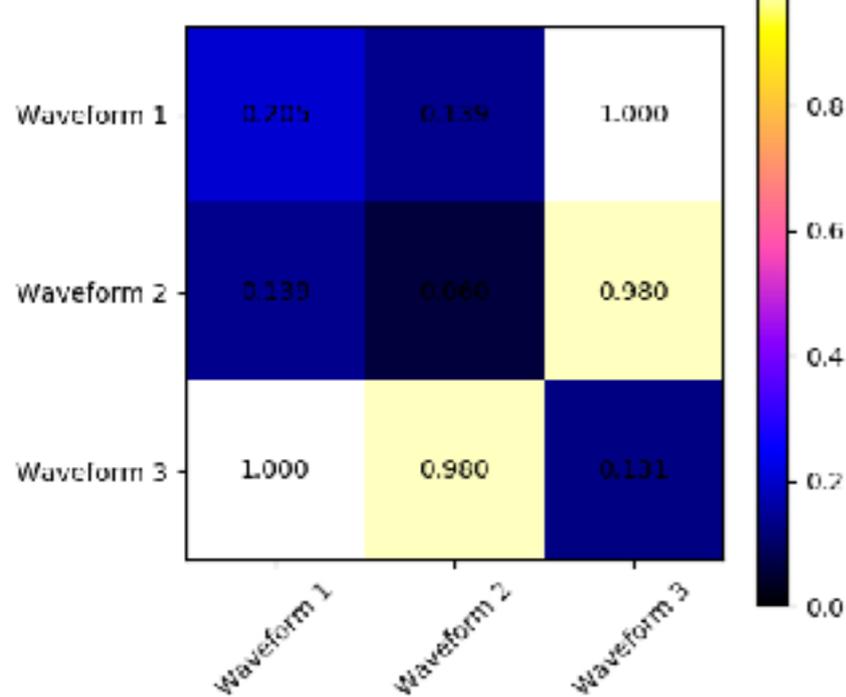

complete linkage

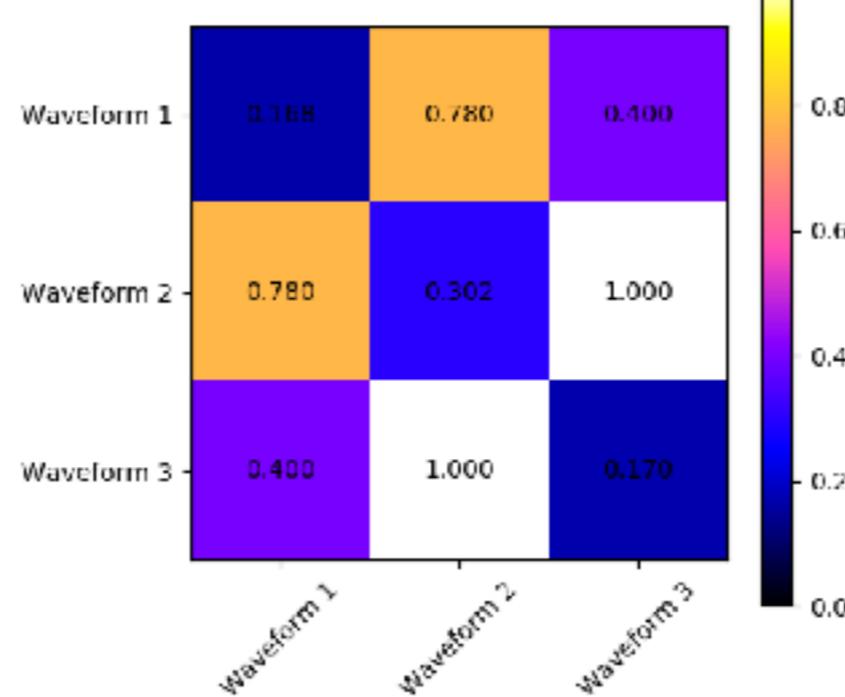

# different metric choices

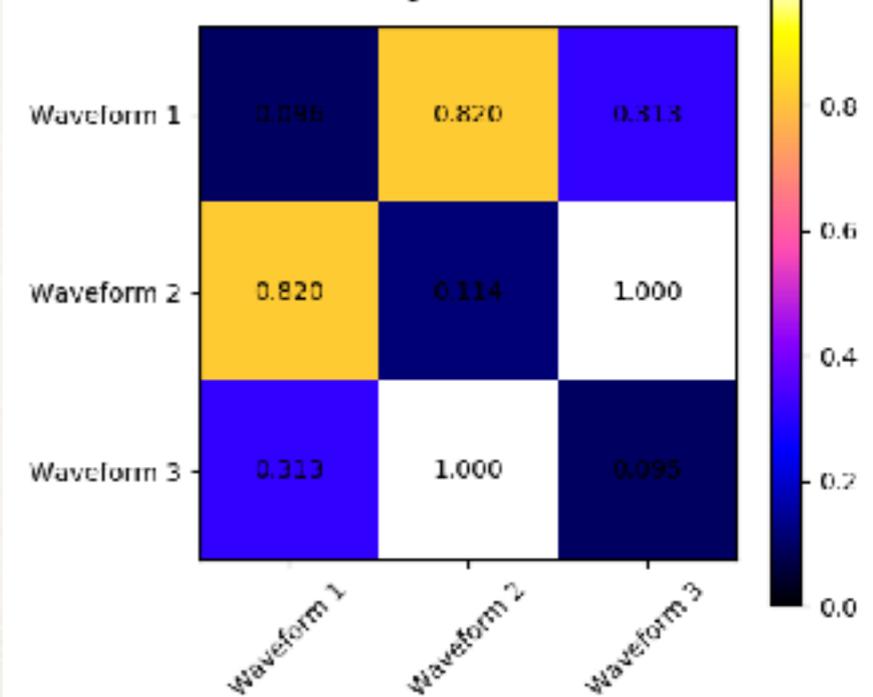

Interclass cosine distances

Interclass euclidean distances

Interclass cityblock distances

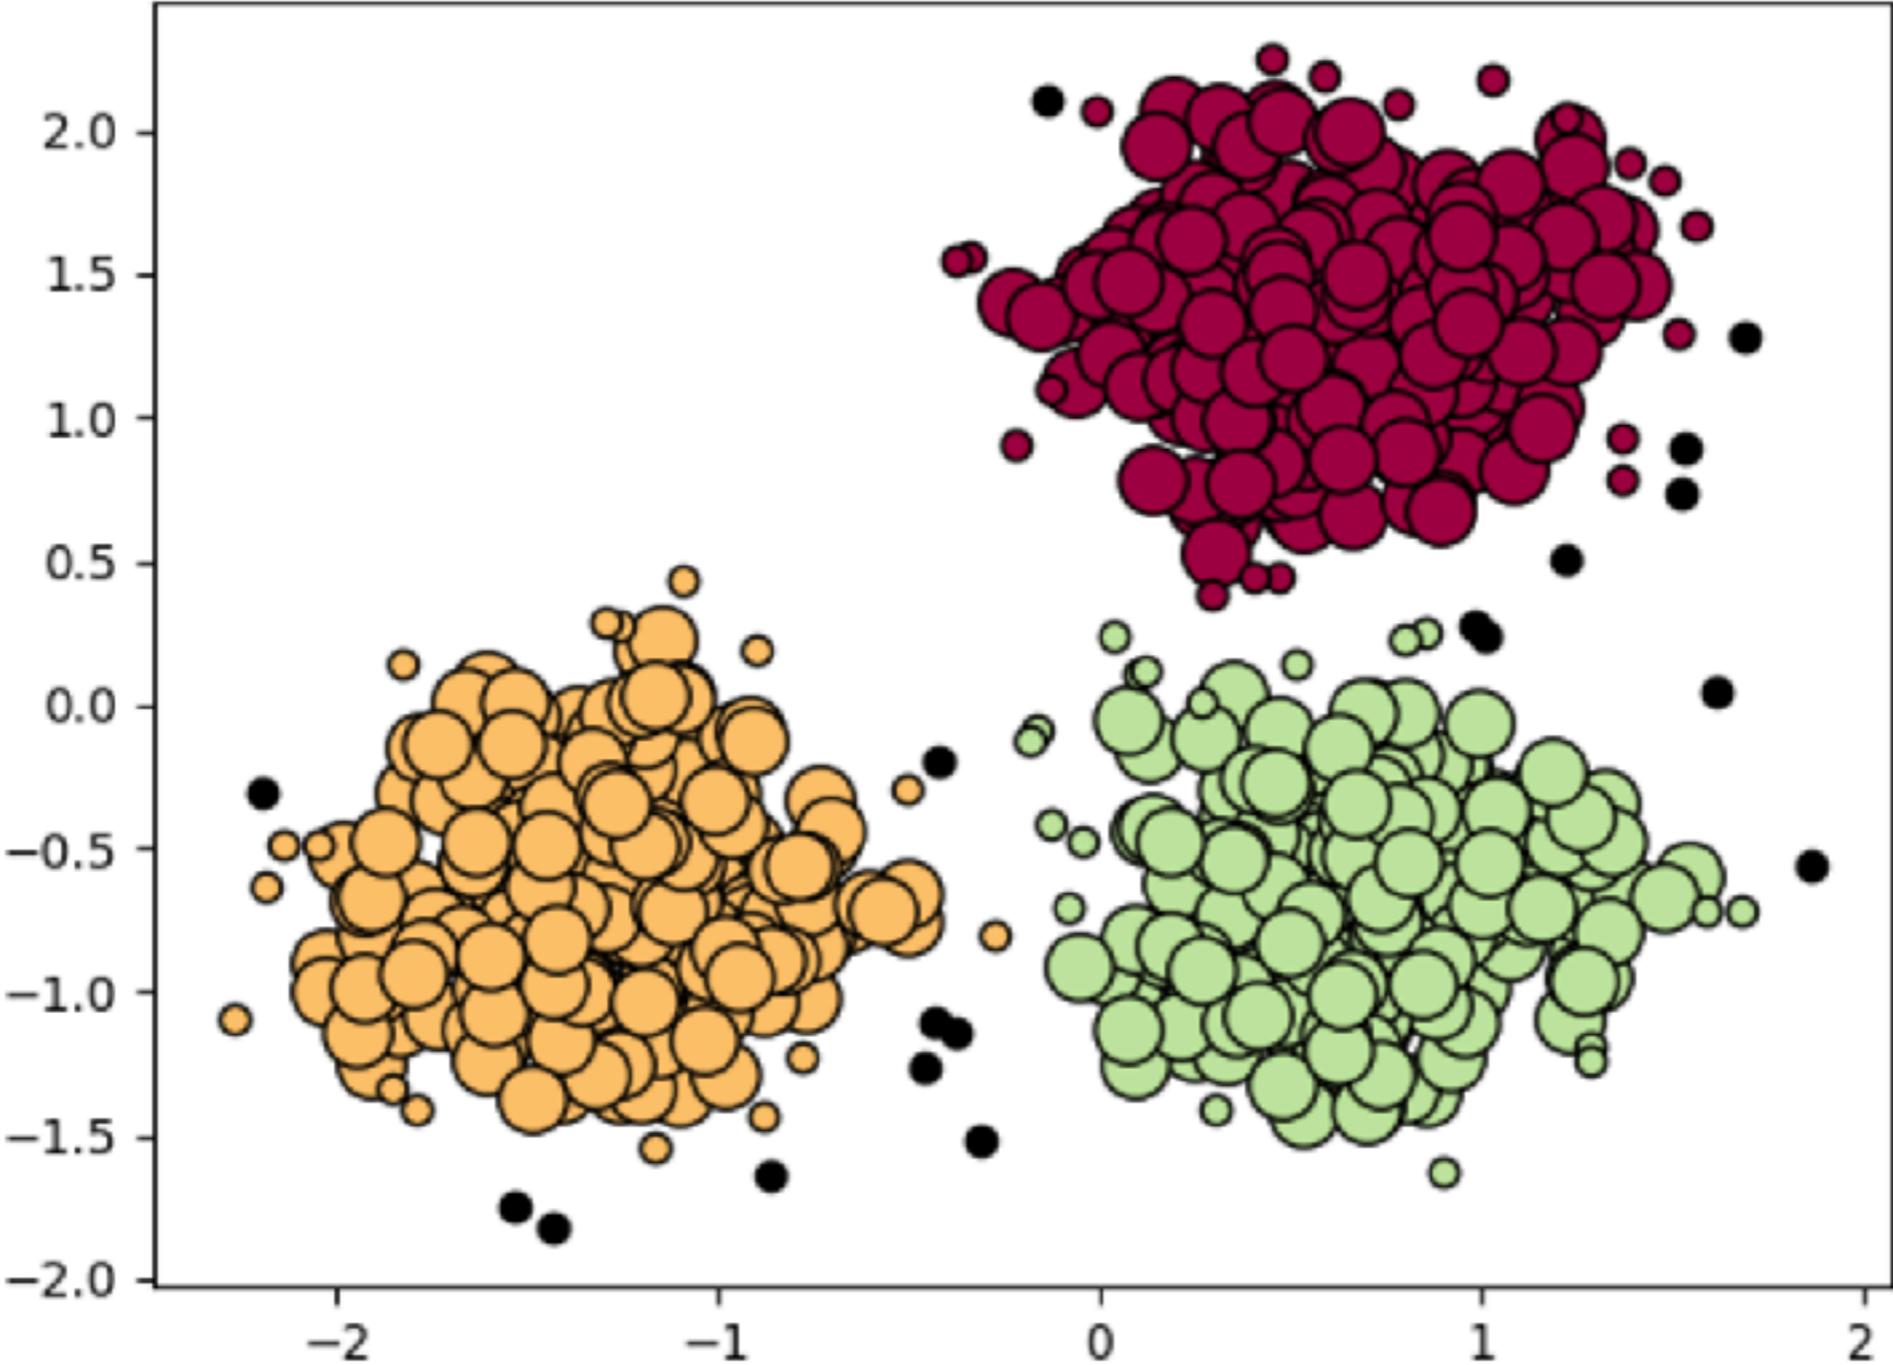

# Density-based clustering algorithms

---

- ❖ Attempts to find regions of high density (clusters) in the data which are separated by regions of low density (boundaries / noise).
- ❖ Can detect clusters of any shape, not just convex.
- ❖ e.g. **DBSCAN**: Find highly dense regions as clusters and assign points in the low-density regions to the cluster they are closer to. Unassigned points are *outliers*.
- ❖ **Use case**: Non-flat geometry, uneven cluster sizes, outliers
- ❖ **Requires**: Quantify density (e.g. set of points for each of which there exists  $m$  number of points at a distance less than  $d$ , in *sklearn*, *min\_samples* and *eps*).
- ❖ **Drawbacks**: Need sharp density gradient to detect clusters, not effective where the gradient is continuous e.g. a mixture of Gaussians.
- ❖ **Variants**: OPTICS, Mean Shift

Estimated number of clusters: 3

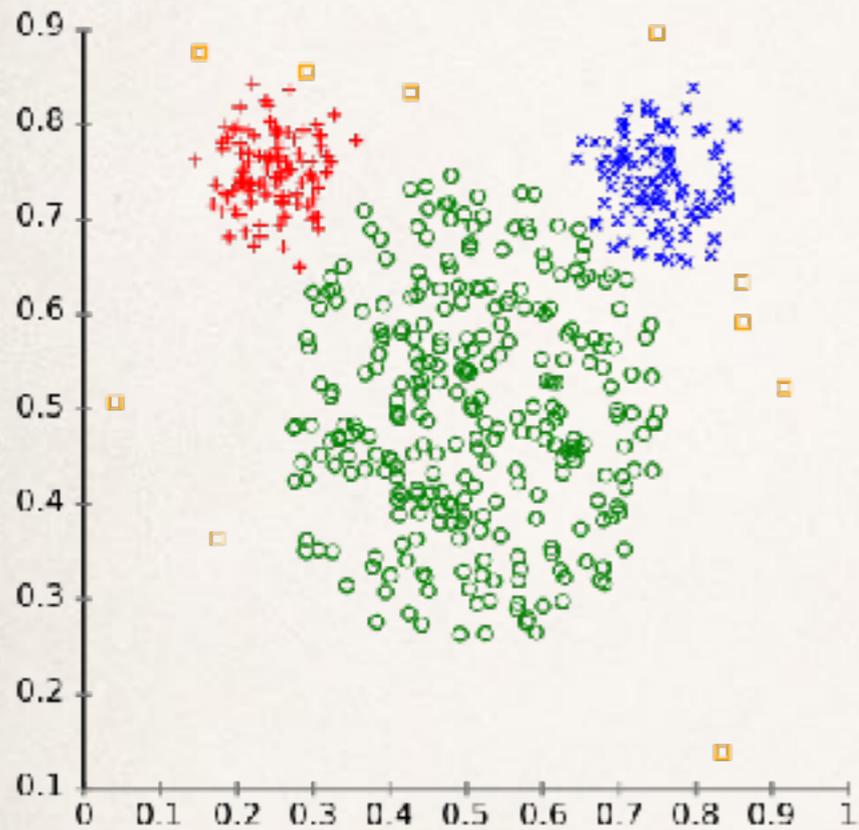

# Probability-based clustering algorithms

---

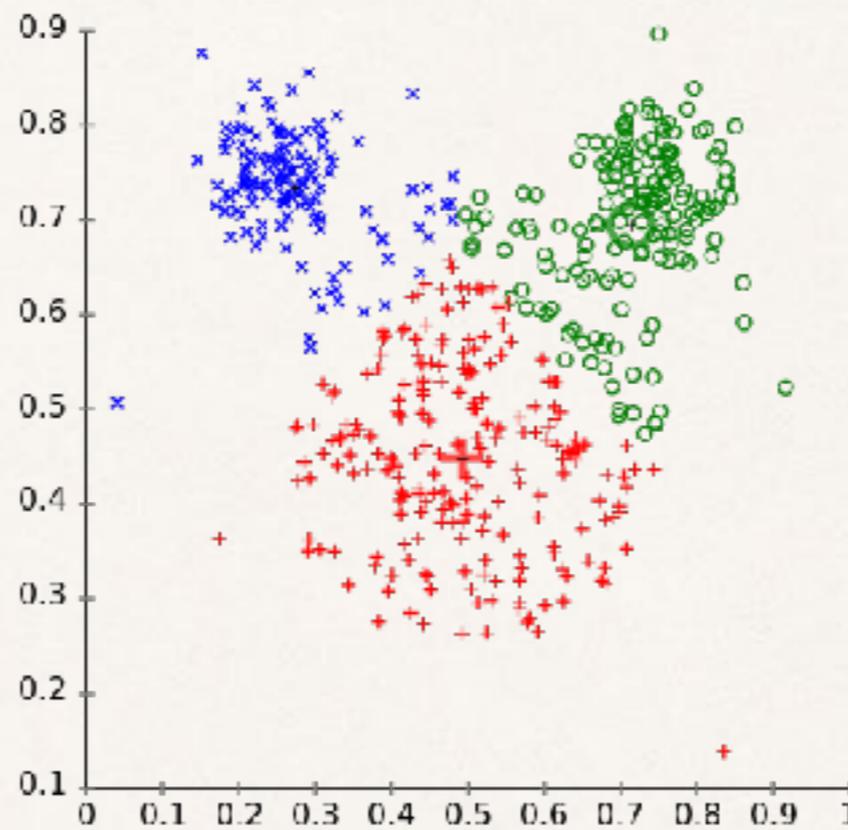

- ❖ Distinct clusters are samples from distinct probability distributions. Assume a distribution model, and try to separate based on the parameter estimates.
- ❖ **Gaussian Mixture model:** The data points are generated from a mixture of a finite number of Gaussian distributions with unknown parameters which are estimated using *Expectation-Maximization* algorithm.
- ❖ Usually overfits unless constrained model is used, e.g. fixing the number of Gaussians (number of clusters), in fact GMM is a generalisation of k-means to include covariance.
- ❖ Can also constrain covariance.
- ❖ **Use case:** Flat geometry, good for density estimation.
- ❖ **Requires:** k (usually), covariance constraint, convergence threshold for EM algorithm, initialization for parameters.

# Different cluster analysis results on "mouse" data set:

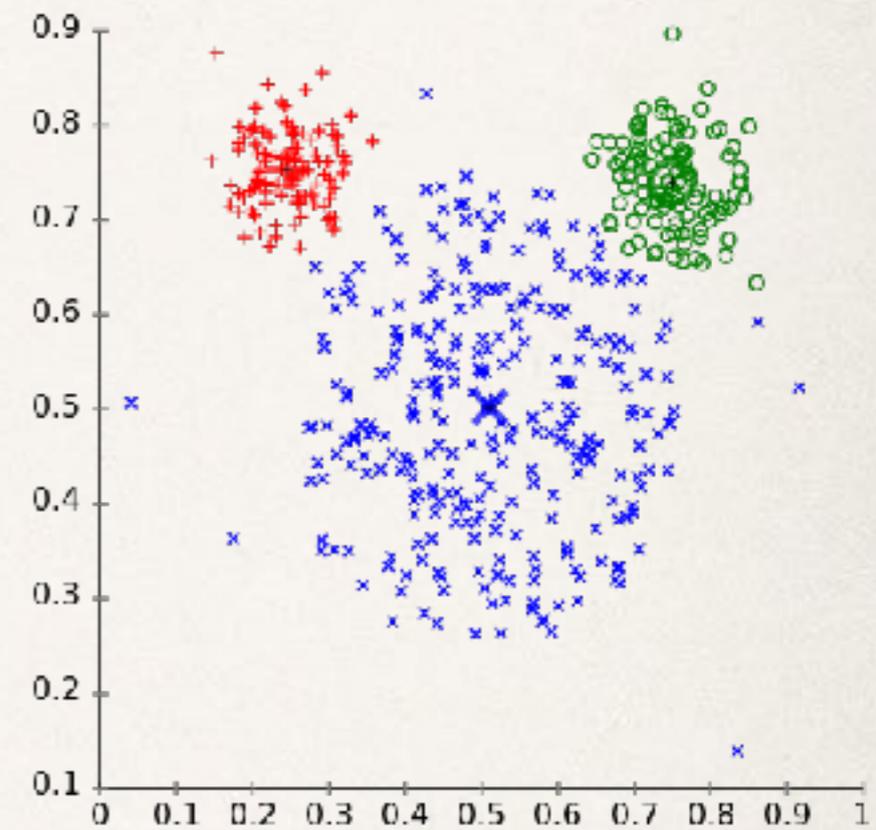

Original Data

k-Means Clustering

EM Clustering

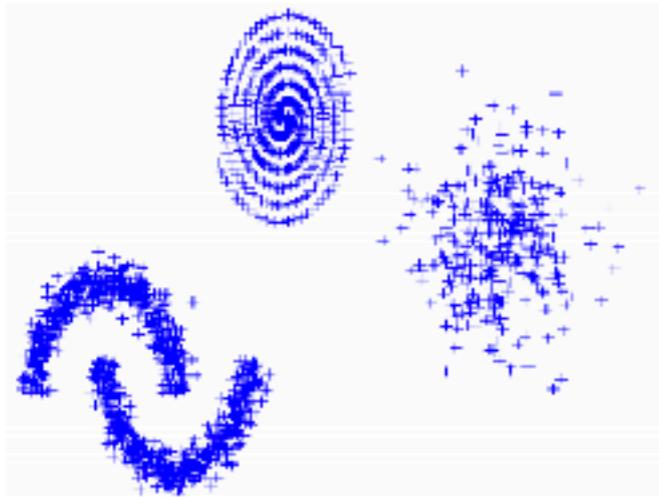

Cluster analysis performed on an artificial dataset ("Mouse", similar to a well-known comic figure) comparing k means and EM clustering results.

# Issues in cluster analysis

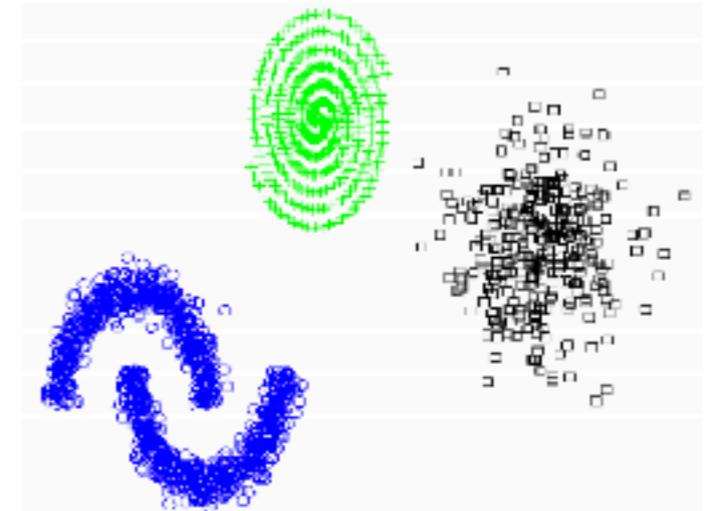

---

- ❖ So many algorithms to choose from, NO systematic-mathematical way to decide. Optimal parameters for the chosen algorithm depends on the dataset and the analytical task at hand.
- ❖ *“The notion of cluster can’t be precisely defined. Clustering is in the eyes of the beholder.”* - **Why so many clustering algorithms,**  
*Vladimir Estivill-Castro*
- ❖ Ability to compare various clustering results and estimate quality of a clustering result.
- ❖ Unsupervised method - lack of ground truth. Evaluation is difficult.

# Clustering

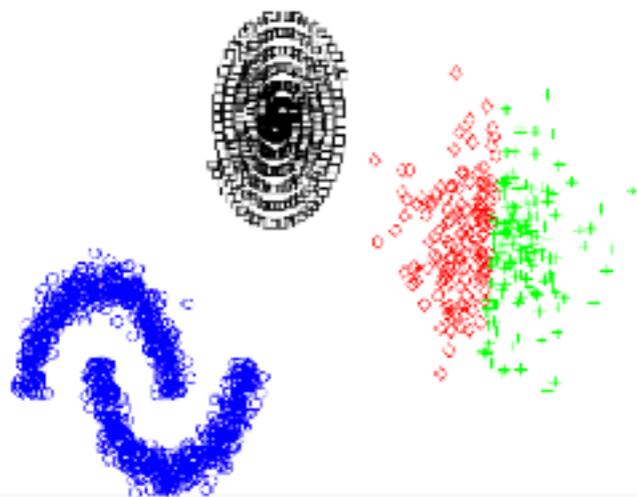

Data

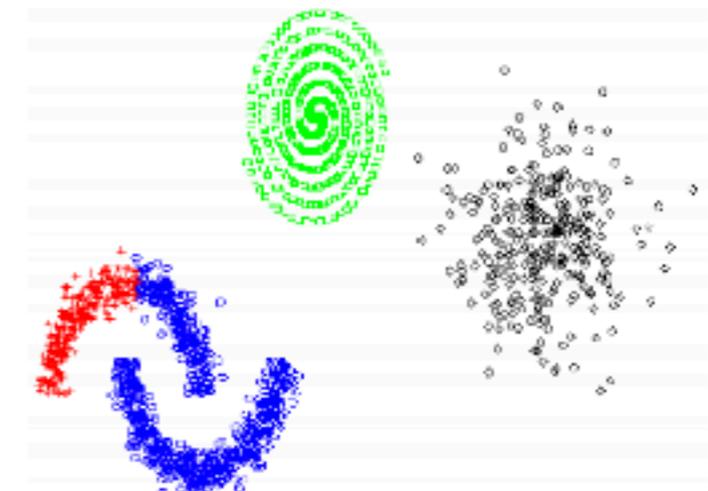

DBSCAN

Different clustering methods output different partitions!

Which method do I pick?

Kmeans

Complete Linkage HAC

# Clustering evaluation metrics

---

- ❖ Difficult task, at least as difficult as clustering (*Pfitzner et al*).
- ❖ **External evaluation:** results are compared with ground truth. Not practical.
- ❖ **Internal evaluation:** results are aggregated into a single statistic. Without ground truth.
- ❖ **Manual evaluation:** human expert makes decision, not practical in this big data paradigm.
- ❖ Internal evaluation with human-in-the-loop ?

# Silhouette coefficient

---

- ❖ The *Silhouette Coefficient* is a measure of how similar a point is to its own cluster compared to other clusters, where a high value indicates that the object is well matched to its own cluster and poorly matched to neighbouring clusters.
- ❖ For a data point  $x$  proposed to be in cluster  $C$ , the *Silhouette Coefficient* is defined as

$$s(x) = \frac{D_x - C_x}{\max(C_x, D_x)}$$

- ❖ where  $C_x$  is the average distance between  $x$  and all other points in  $C$ , and  $D_x$  is the distance between  $x$  and all the points in the cluster nearest to  $x$ .
- ❖ The *Silhouette coefficient* for the whole clustering is defined to be mean of the values for all the data points. The value lies in  $(-1, 1)$  where the higher the value of the coefficient, the better the clustering .
- ❖ **Reference:** P. J. Rousseeuw *Silhouettes: A graphical aid to the interpretation and validation of cluster analysis*. Journal of Computational and Applied Mathematics, 20:53–65, 1987 ([sklearn.metrics.silhouette\\_score](https://scikit-learn.org/stable/modules/generated/sklearn.metrics.silhouette_score.html))

# Calinski-Harabaz index

---

- ❖ The *Calinski-Harabaz index* of a clustering is defined as the ratio of the between-cluster variance and the within-cluster variance.
- ❖ Well-defined clusters have higher between-cluster variance and lower within-cluster variance, thus higher value of the index.
- ❖ For  $k$  clusters,  $CZ(k) = \text{Total inter-cluster variance} / \text{Total intra-cluster variance}$ , where

$$\text{Inter-cluster variance} = \sum_{i=1}^k n_i \|m_i - m\|^2$$
$$\text{Intra-cluster variance} = \sum_{i=1}^k \sum_{x \in C_i} \|x - m_i\|^2$$

- ❖ Here  $i$ -th cluster,  $C_i$  has mean  $m_i$  and contains  $n_i$  elements, and  $m$  is the overall mean of the data.
- ❖ **Reference:** M. Kozak. *“A dendrite method for cluster analysis” by Calinski and Harabaz: A classical work that is far too often incorrectly cited.* Communications in Statistics - Theory and Methods, 41(12):2279–2280, 2012 ([sklearn.metrics.calinski\\_harabaz\\_score](https://scikit-learn.org/stable/modules/generated/sklearn.metrics.calinski_harabaz_score.html))

# Davies-Bouldin coefficient

---

- ❖ Similar to *Calinski-Harabaz index*, is defined as the average over all clusters the ratio of within-cluster dispersion and the pairwise between-cluster dispersion.

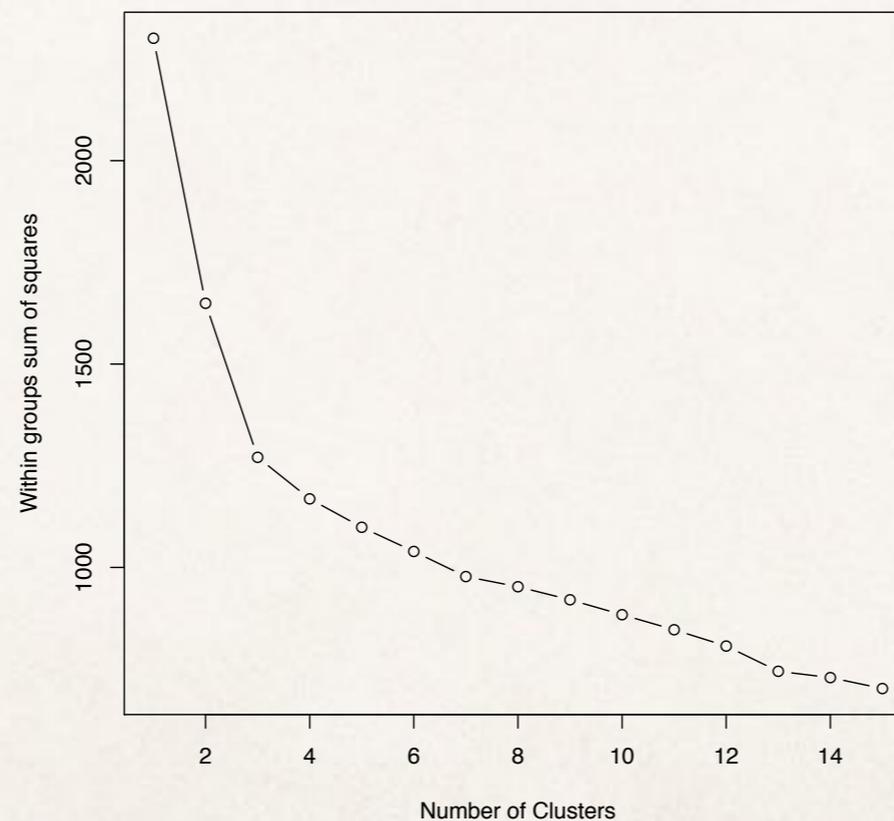

$$DB(k) = \frac{1}{k} \sum_{i=1}^k \max_{i \neq j} DB_{ij}$$
$$DB_{ij} = \frac{\bar{D}_i + \bar{D}_j}{\bar{D}_{ij}}$$

- ❖ Here  $\bar{D}_i$  is the average distance between each point in the i-th cluster and its centroid, and  $\bar{D}_{ij}$  is the average distance between the centroids of the i-th and the j-th cluster.
- ❖ Smaller the *Davies-Bouldin index*, better the clustering results are.
- ❖ **Reference:** D. L. Davies and D. W. Bouldin. *A cluster separation measure*. IEEE Trans. Pattern Anal. Mach. Intell., 1(2):224–227, Feb. 1979.

# Gap statistic

---

- ❖ The *elbow method*, where a metric (usually within to between-cluster distance ratio) is plotted against an internal parameter, is a popular and intuitive method to find the optimal value of the parameter. *Tibshirani et al* provided a statistical formulation of this technique and defined *gap statistic*.
- ❖ The idea is to consider clustering of random permutations of the data to observe how they compare with a null reference distribution of data with no clustering structure.

- ❖ **Reference:** R. Tibshirani, G. Walther, and T. Hastie. *Estimating the number of clusters in a dataset via the gap statistic*. 63:411–423, 2000.

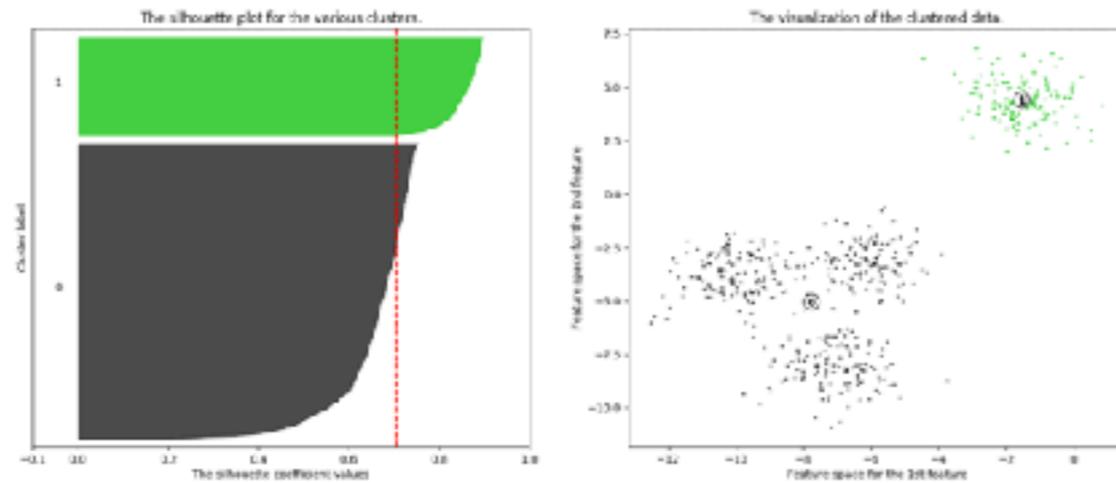

# Sdb\_w

---

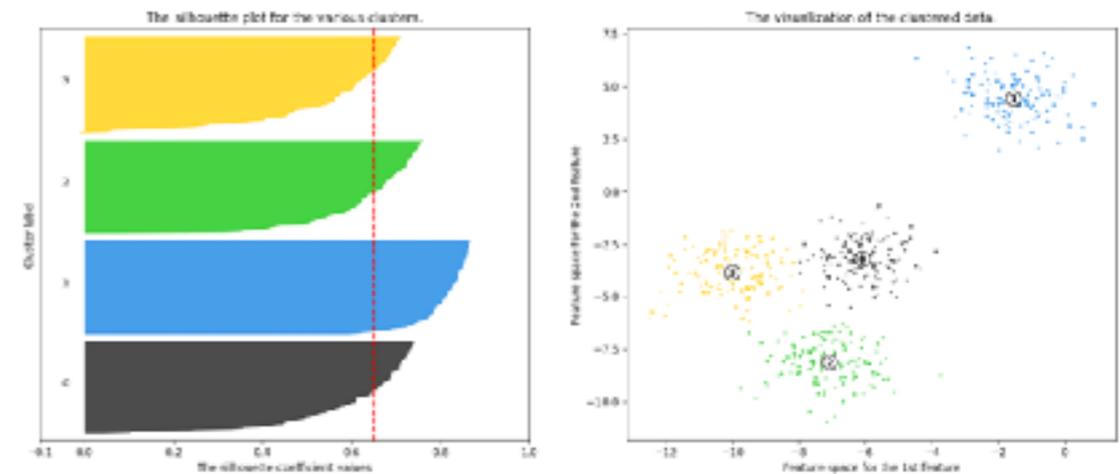

- ❖ *Sdb\_w* attempts to measure quality by taking into consideration the *compactness, separation, and the density* of the clusters .
- ❖ Relies on the notion of the *density of a point  $x$  relative to a pair of clusters* which is equal to the number of points in these clusters which are inside a ball centered at  $x$ .
- ❖ Defined under the assumption that for each pair of clusters, the density of at least one of the centroids must be greater than the density of their midpoint to have a good clustering
- ❖ Reference: M. Halkidi and M. Vazirgiannis. *Clustering validity assessment: Finding the optimal partitioning of a data set*. In Proceedings of the 2001 IEEE International Conference on Data Mining, ICDM '01, pp. 187–194. IEEE Computer Society, Washington, DC, USA, 2001

# Selecting number of clusters using Silhouette analysis

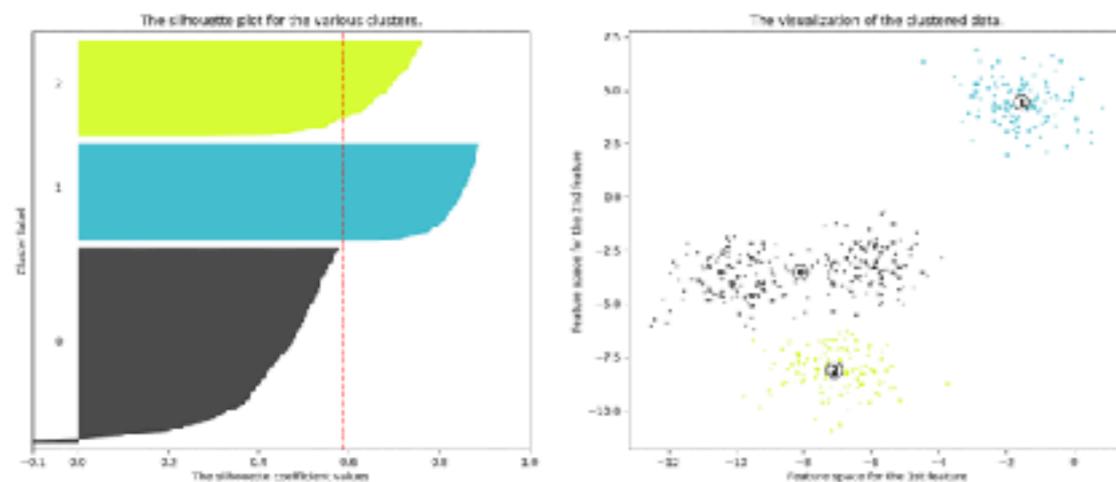

Silhouette analysis for KMeans clustering on sample data with n\_clusters = 2

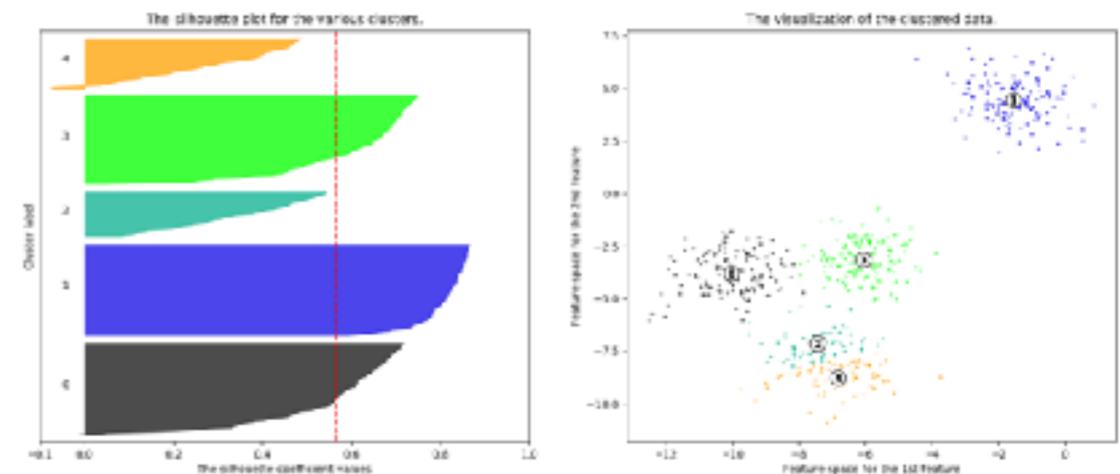

Silhouette analysis for KMeans clustering on sample data with n\_clusters = 4

Silhouette analysis for KMeans clustering on sample data with n\_clusters = 3

Silhouette analysis for KMeans clustering on sample data with n\_clusters = 5

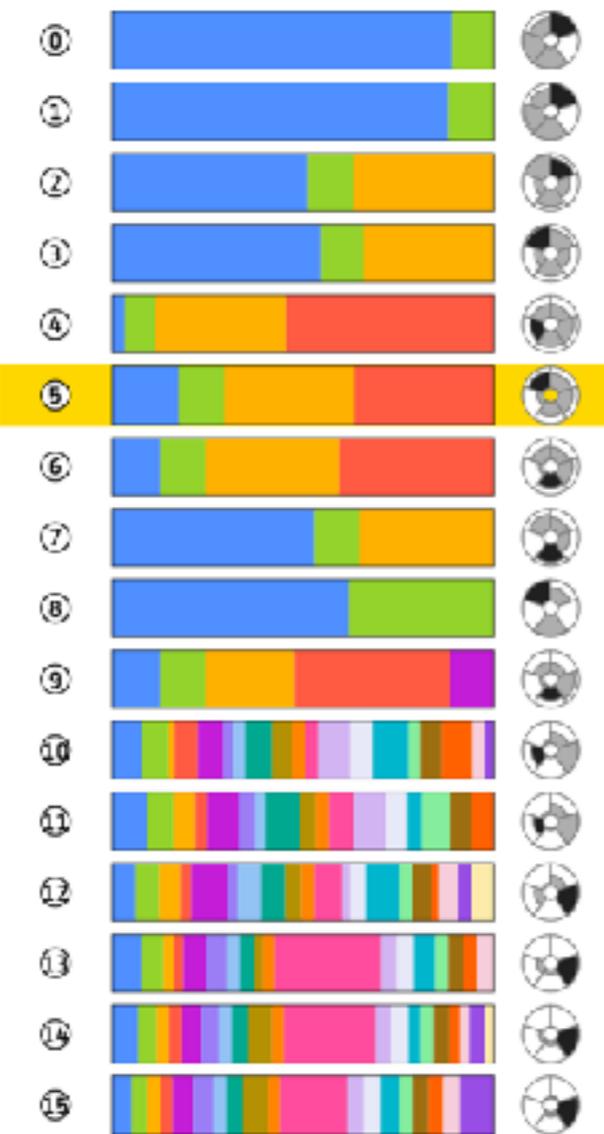

k=3,5 are not good options!!  
Which is the best (most optimal) value of k?

# Clustervision

---

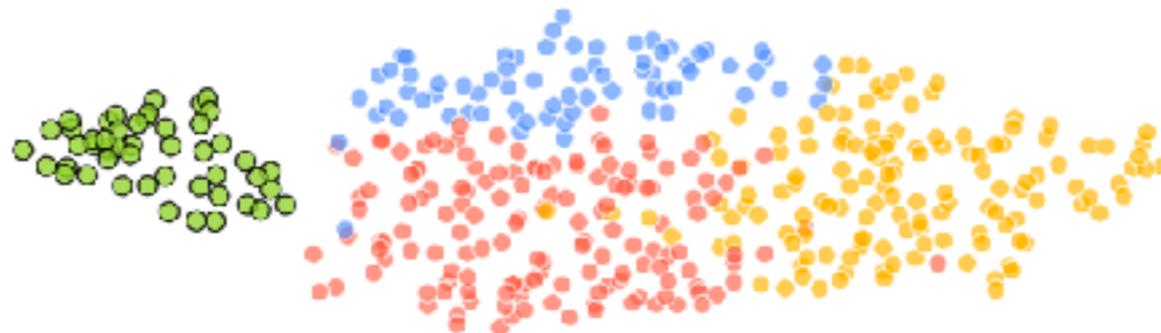

- ❖ *Clustervision* is a visual analytical tool that helps ensure data scientists find the right clustering among the large amount of techniques and parameters available.
- ❖ Developed by researchers at [IBM Watson Research Center](#).
- ❖ The system clusters data using a variety of clustering techniques and parameters and then ranks clustering results utilizing five quality scoring metrics.
- ❖ The visual user interface allows users to find high quality clustering results, explore the clusters using several coordinated visualization techniques, and select the cluster result that best suits their task.
- ❖ To appear at IEEE Vis October 2017.

# Randomness in clustering

---

- ❖ Many clustering algorithms like k-means, GMM use a random initialization.
- ❖ Since these algorithms are approximate solutions to the optimization problem, they attempt to find a local minima.
- ❖ Which local minima is found, depends on the initial state, and thus we can get different results for multiple runs on same data, using same algorithm and its parameters.

- ❖ Also makes difficult to compare the clustering results from different models.

# Consensus clustering

---

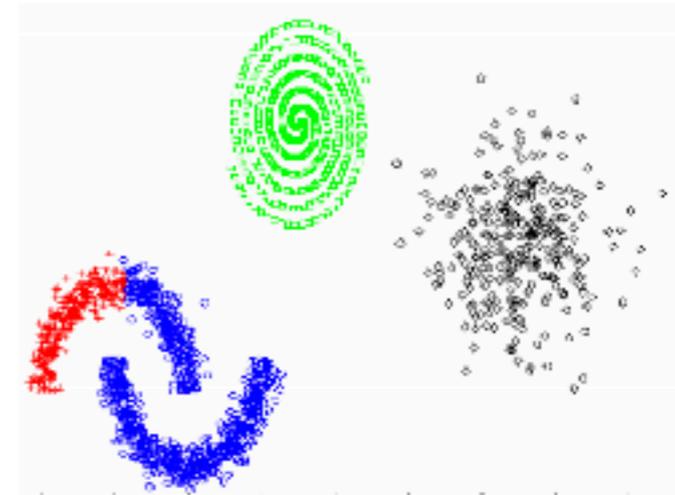

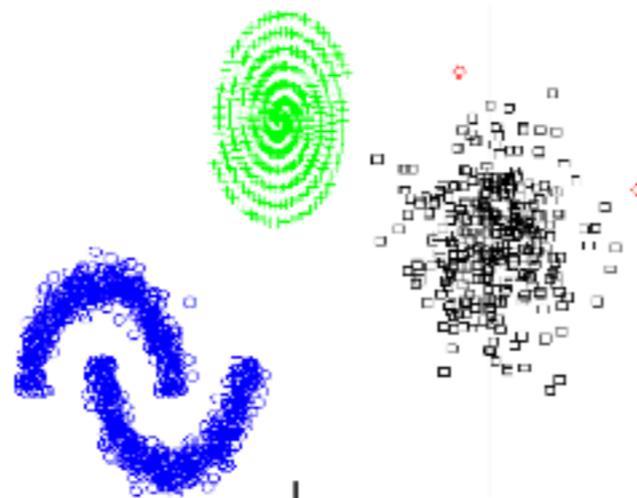

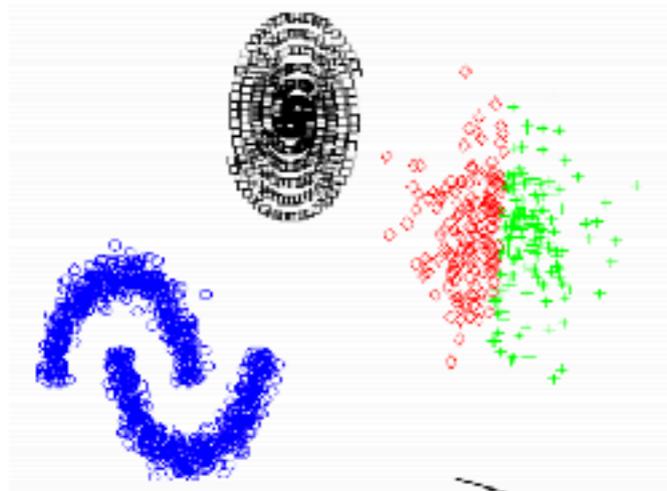

- ❖ One way to get better hold of the sensitivity to random initialization is to do multiple runs of the clustering algorithm, and observe the differences between the runs.
- ❖ Ideally, define a statistic which quantifies the differences among the results of different runs in the ensemble.
- ❖ First, define the *consensus matrix* whose entries reflect the probability that two different data items belong to the same cluster. Perform clustering  $m$  times, then the  $ij$ -th entry in the consensus matrix  $C_{ij} = \#(i \text{ and } j \text{ are in same cluster})/m$
- ❖ Define *dispersion* of the clustering as 
$$\rho = \frac{1}{n^2} \sum_{i=1}^n \sum_{j=1}^n 4 * \left( C_{ij} - \frac{1}{2} \right)^2 .$$
- ❖ The value of the coefficient is 1 for a perfect consensus matrix (all entries 0 or 1). Ideally we want this value to be as close to 1 as possible. This indicates that the different clusterings in the ensemble are statistically similar and are thus robust of the random initializations.

# Consensus clustering

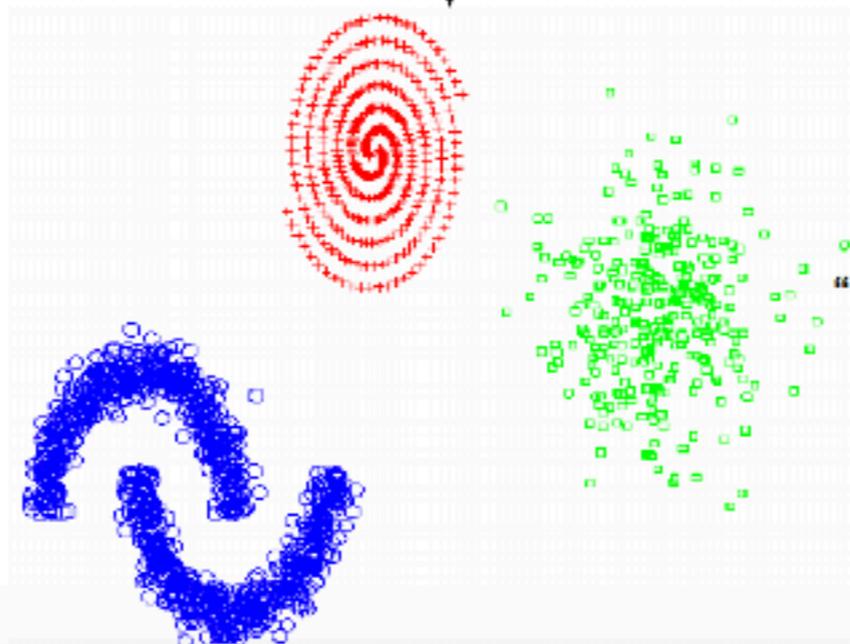

---

- ❖ This can also be used as a clustering evaluation metric and thus can be used to compute the optimal number of clusters. Compute dispersion for different values of  $k$  and then choose  $k$  with maximal value of dispersion.
- ❖ Another such metric is *cophenetic correlation*.
- ❖ If multiple clusterings have been obtained for a given dataset e.g. for different algorithms, same algorithm different parameters, different initialization etc. it's desirable to obtain a single clustering which is an aggregate of all the runs in the ensemble. Such a clustering, called *consensus clustering*, provides a reconciliation of clusterings from different sources.
- ❖ Many different ways to compute the consensus clustering.

# Reconcile!

Consensus

"Close" to all input partitions

# Consensus clustering computation

---

- ❖ The rows of the consensus matrix provides a vector representation for the data points in terms of how they were clustered across multiple runs.
- ❖ Compute the point-wise similarity.
- ❖ Various metrics like cosine, Euclidean, KL-divergence etc. can be used to compute the similarity.
- ❖ Now we perform another clustering on the similarity matrix to obtain the consensus.
